Aircraft

Animal

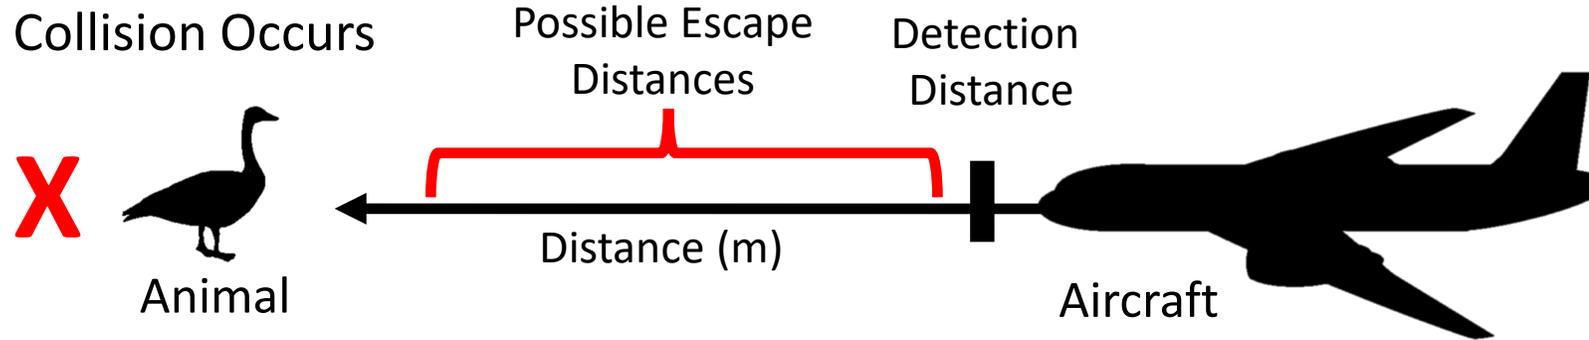

Increasing the distance at which an animal detects an approaching aircraft with lights on can provide more time for the animal to escape.

Detection always precedes escape behavior. If an animal cannot outrun the threat, they must escape at a longer distance.

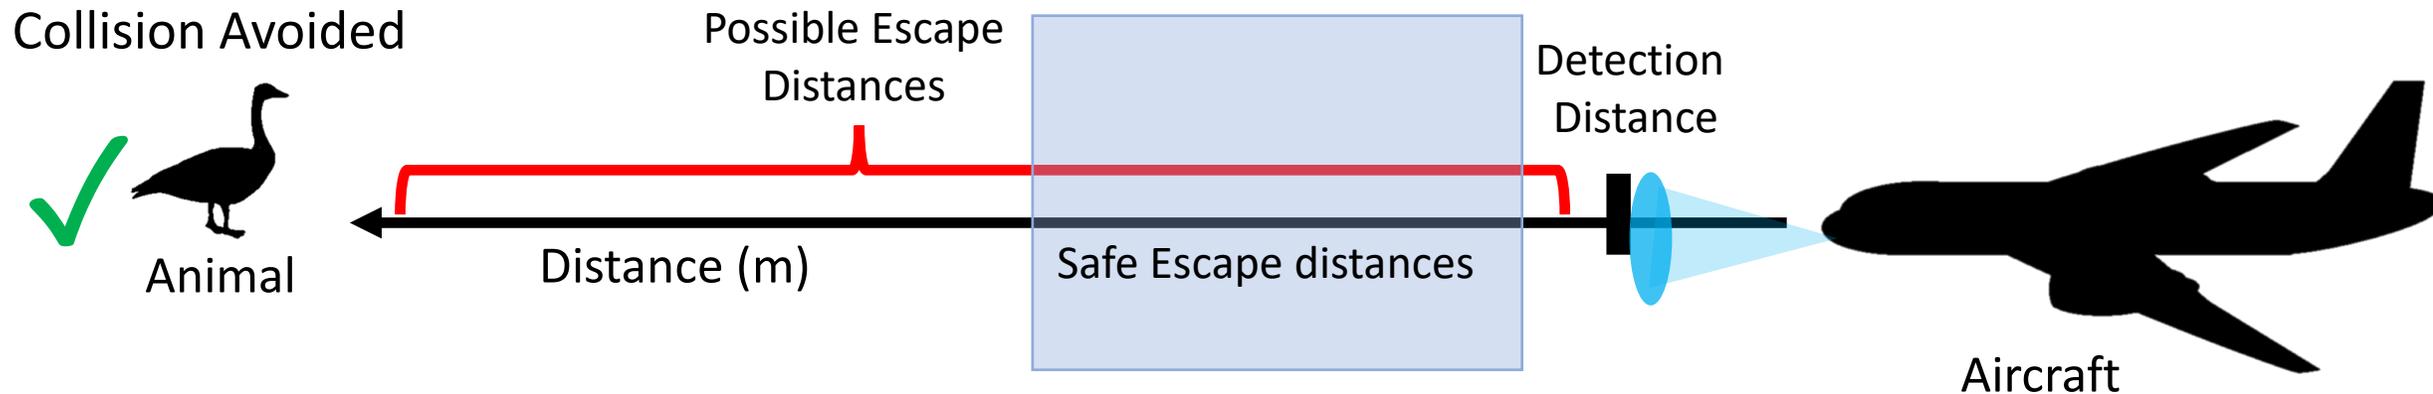

Scenario 1:

Shorter detection distance

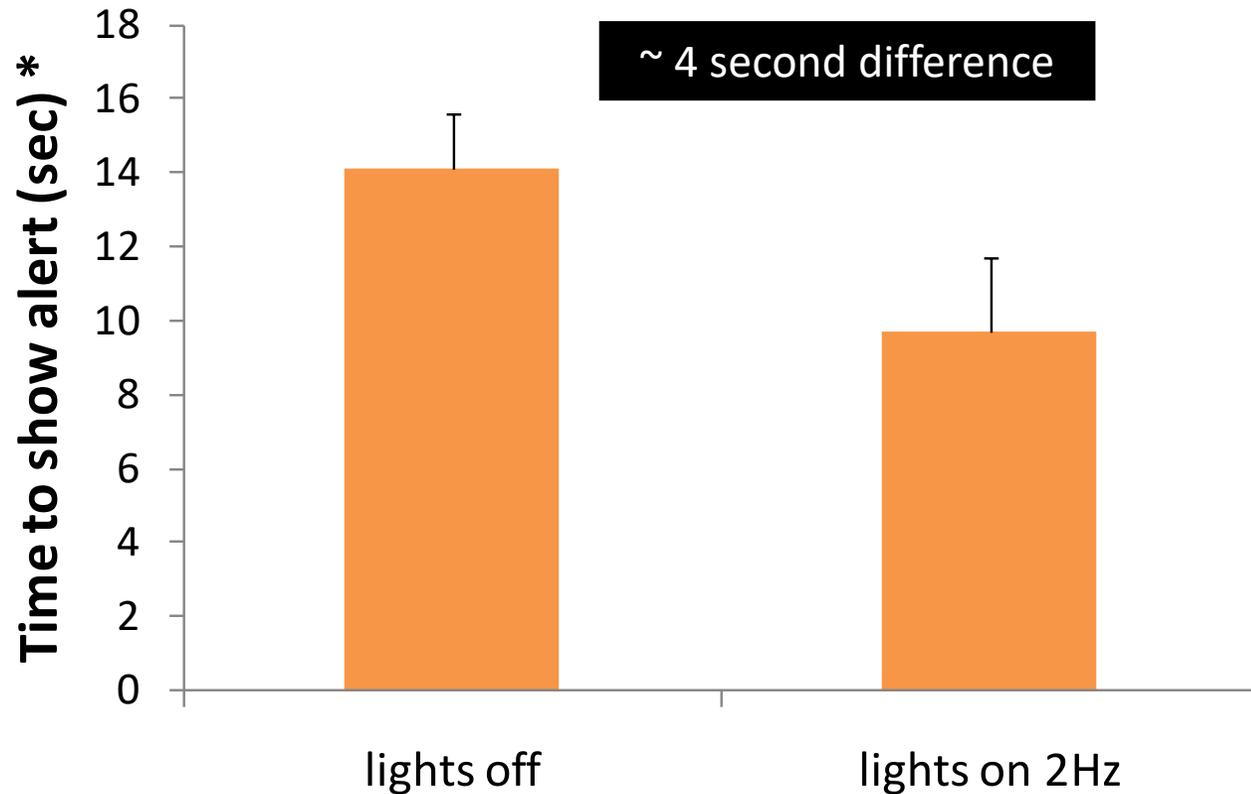

Scenario 2:

Longer detection distance

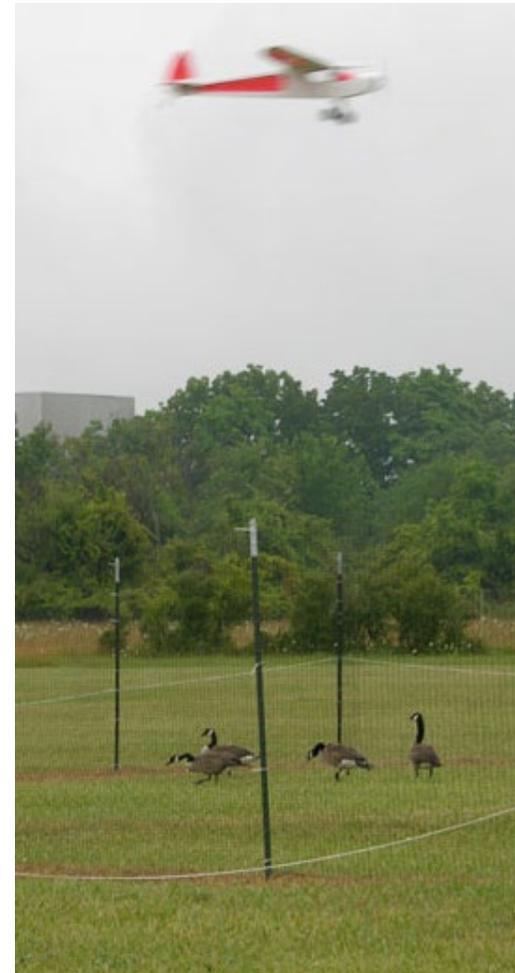

Main Assumption:

- Lights onboard a vehicle will trigger detection and alert response earlier than an aircraft with lights off.

* *time from initiation of an alert behavioral response to the vehicle reaching the end point of the approach.*

Blackwell et al. 2012

Goal of the Study:

- **Evaluate the relative performance of LED lights (varied in color (nm) and frequency) tuned to the Canada goose eye at evoking avoidance behavior**

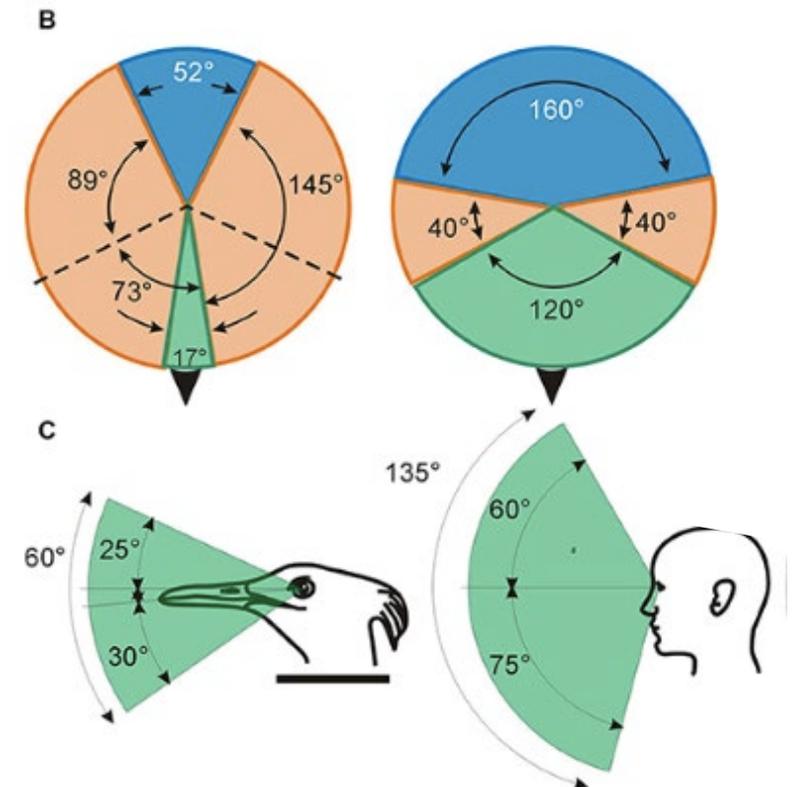

Why tune lights to the bird eye?

Avian vision differs drastically from human vision

- Visual Coverage
- Spatial visual resolution
- Temporal visual resolution

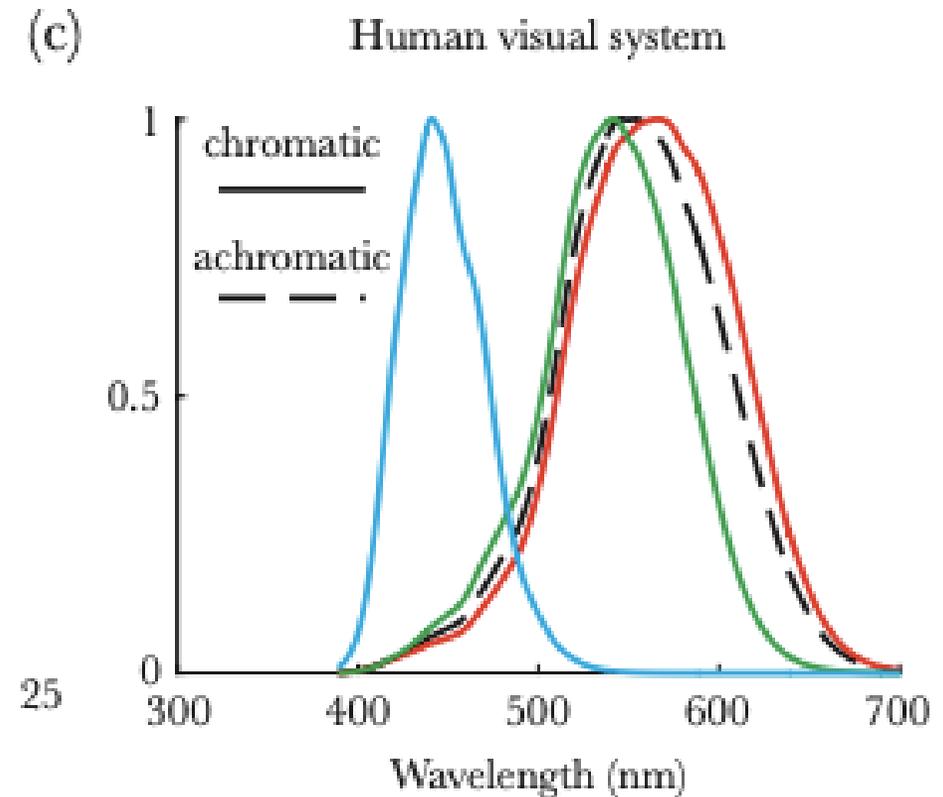

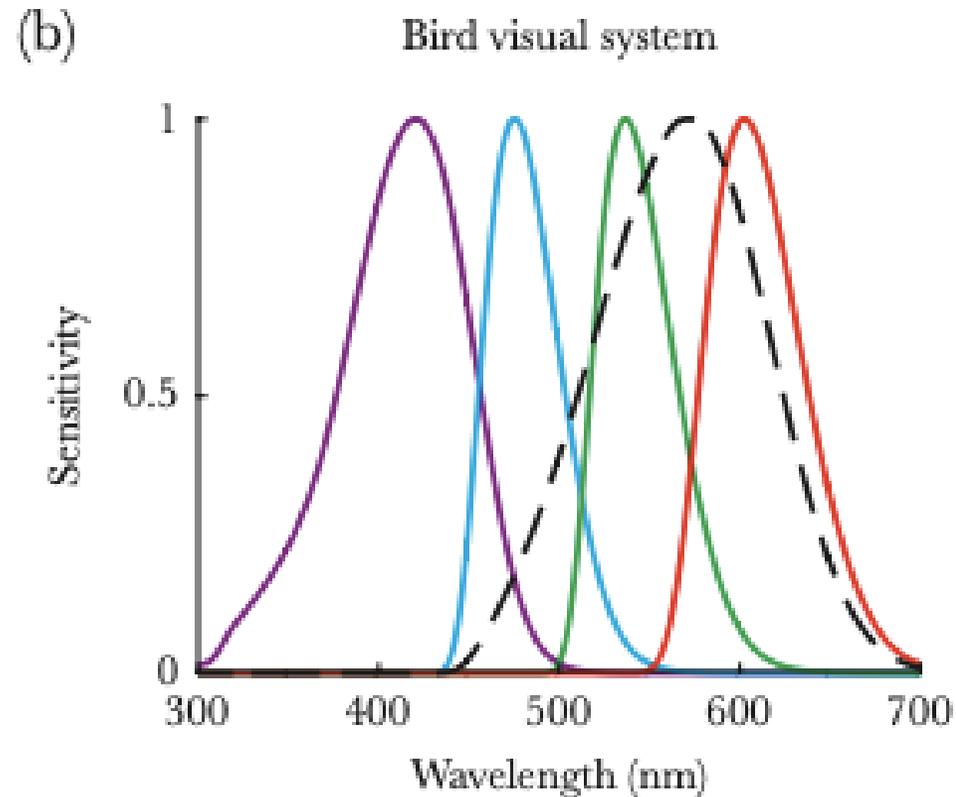

Visual Coverage

Why tune lights to the bird eye?

Avian vision differs drastically from human vision in terms of color perception

Photoreceptor Sensitivity

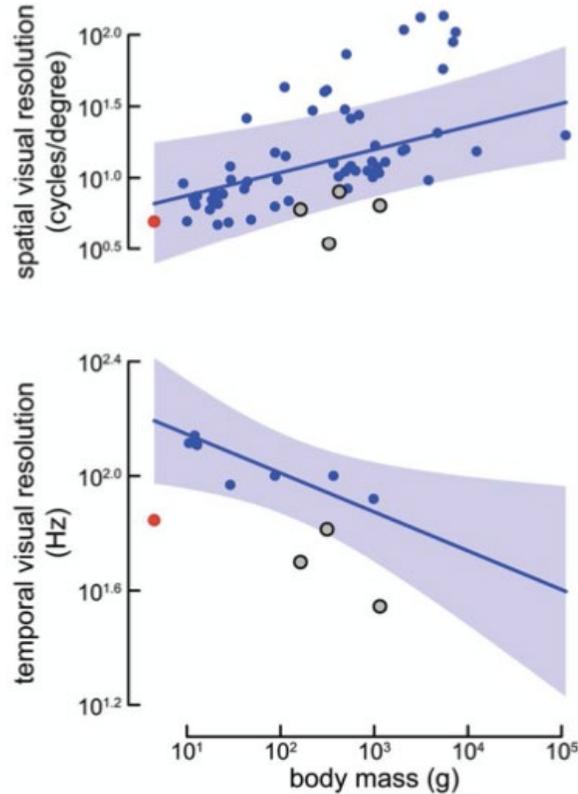

25

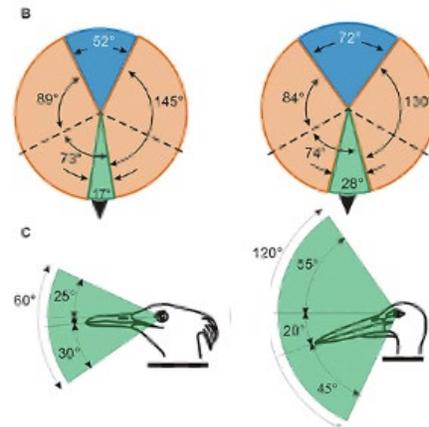

Why tune lights to the Canada goose eye?

Visual perception differs drastically between bird species

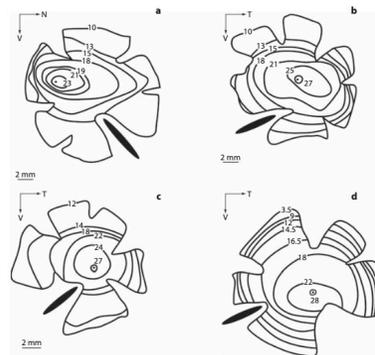

Spatial and Temporal Visual Resolution

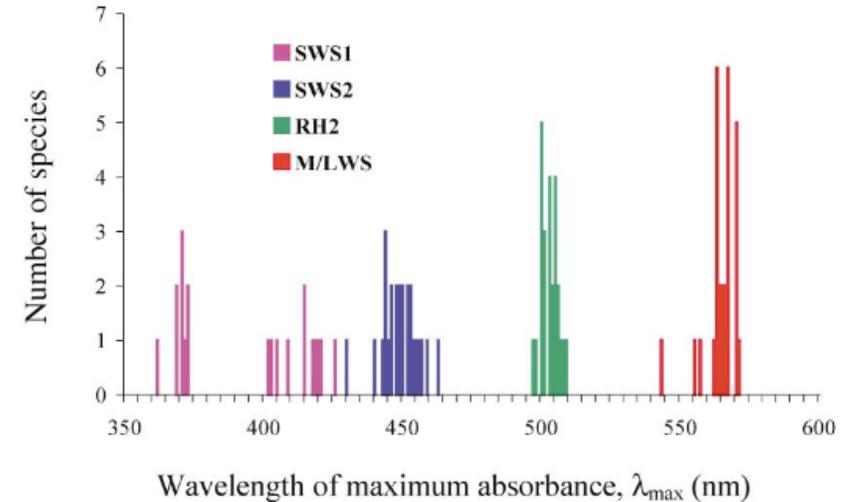

Visual Coverage

Retinal Topography

Peak Absorbance of photoreceptors

Tuning lights to Canada Goose eye required characterizing its visual anatomy and physiology

We used a Canada Goose visual model

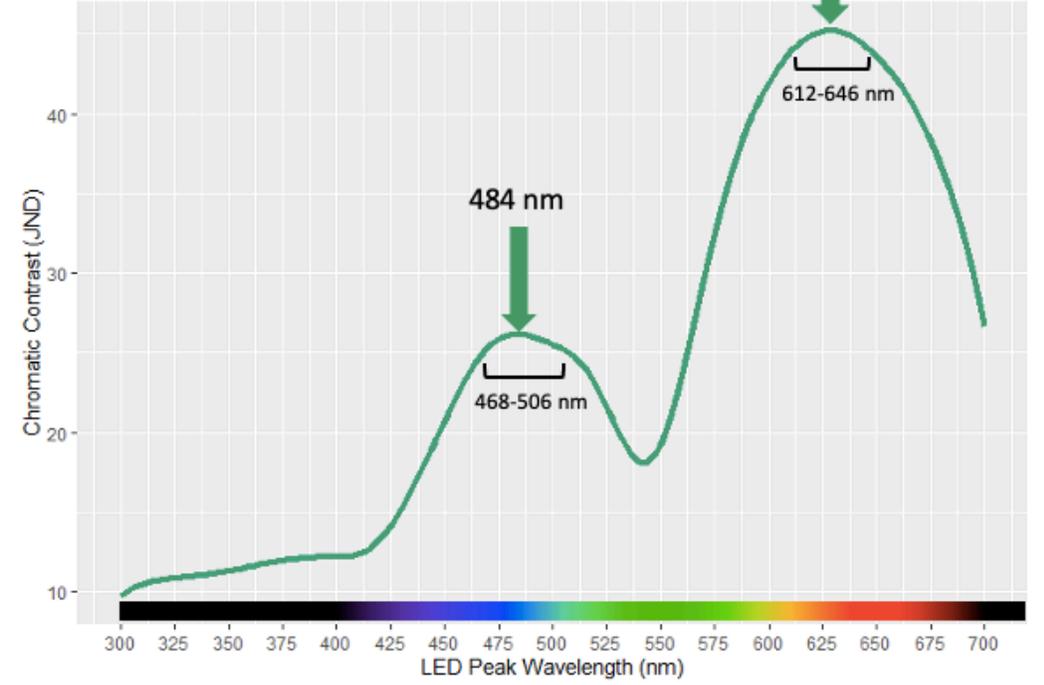

Canada Goose Photoreceptor Relative Densities

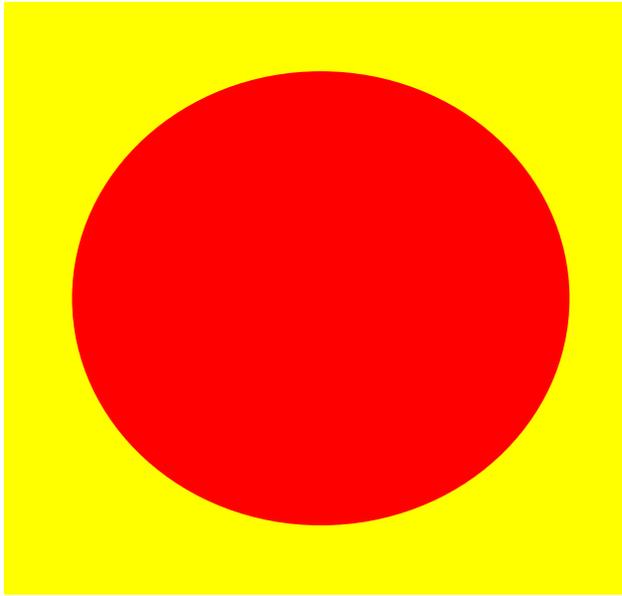

Canada Goose Sensitivity Curves

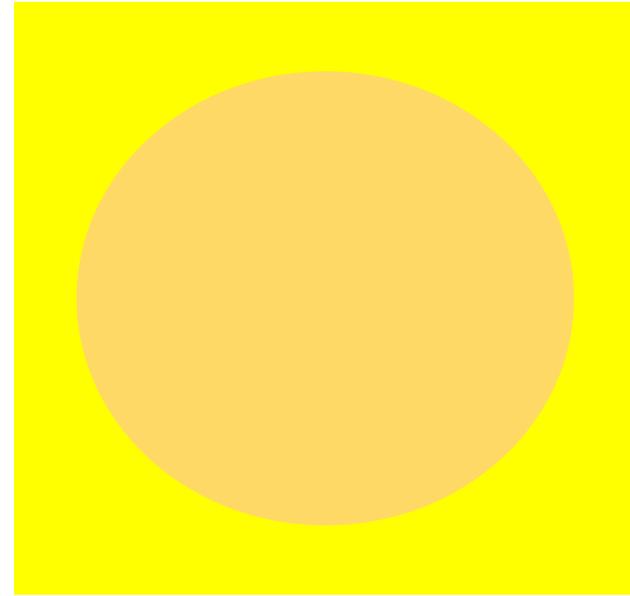

Chromatic Contrast of LED Lights

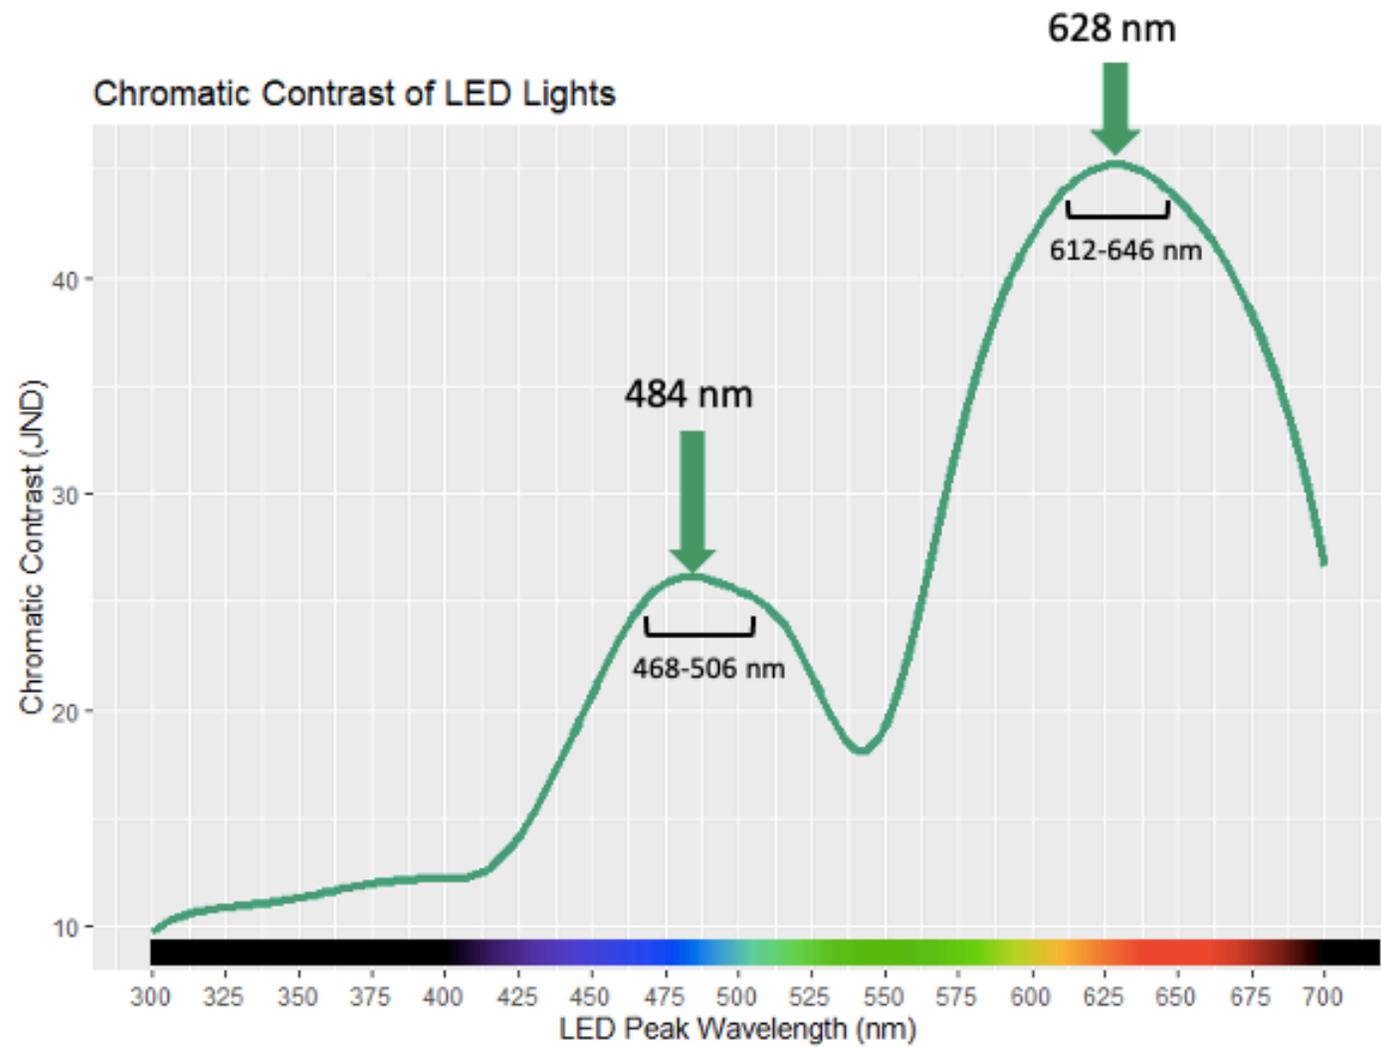

Relatively Higher Chromatic
Contrast (Larger JND value)

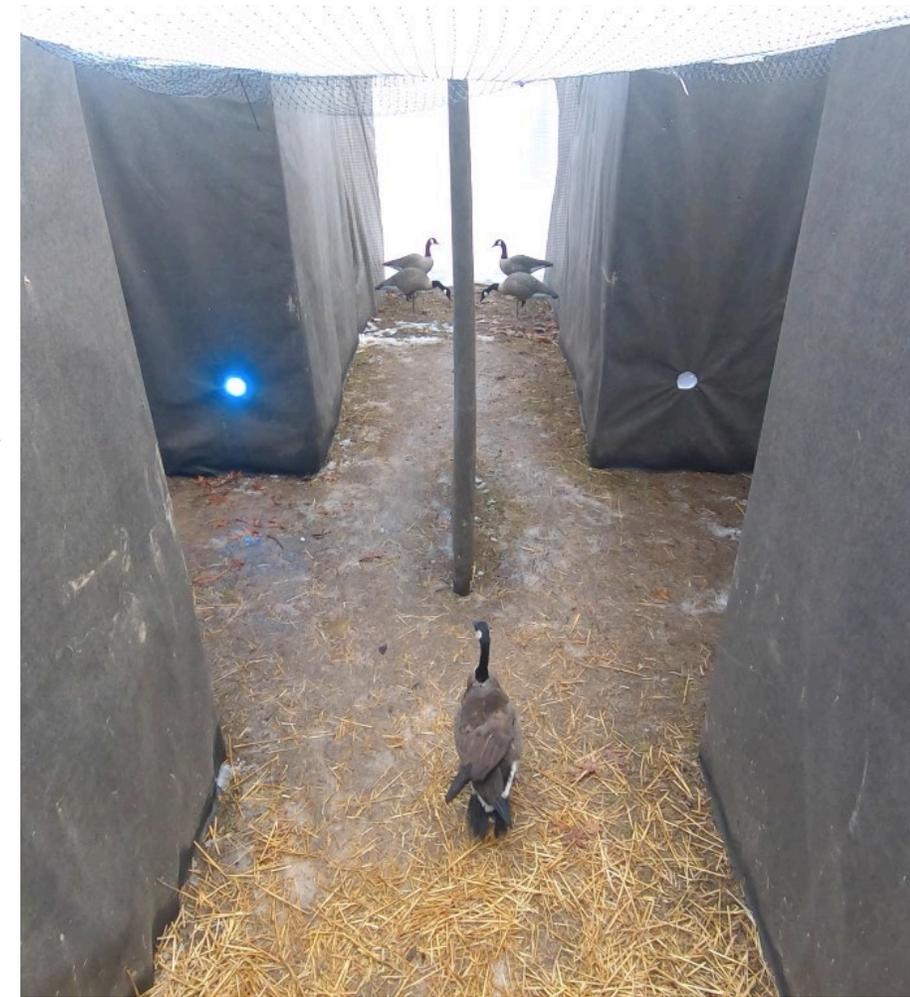

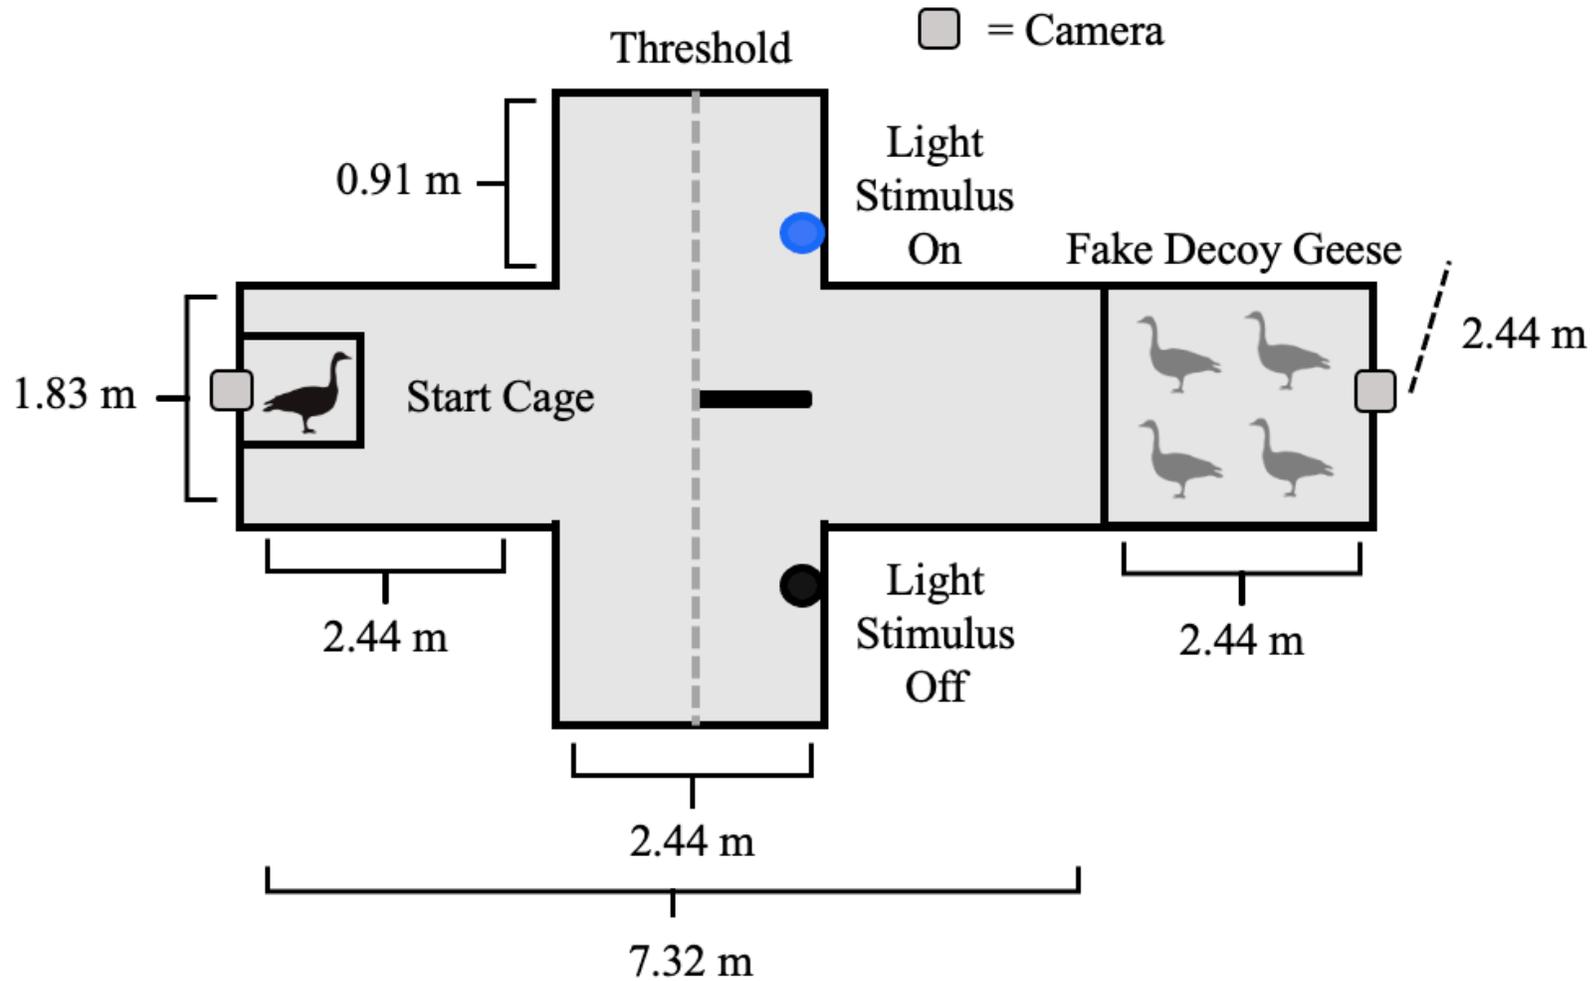

Relatively Lower Chromatic
Contrast (Larger JND value)

Experimental Design: Single Choice Test

Experimental Design: Single Choice Test

Sample Size

- 23 geese, exposed to different color & frequency treatments

Dependent Variables

- Latency to respond to the lights
- Body movement rate
- Light avoidance
- Survival

Steady

Independent Variables

- Light Color (Blue (471 nm) vs. Red (627nm))
- Light Frequency (Steady vs. Pulsing (2 Hz))

Covariates

- Light Position, Trial Order, Light Intensity (Lux)

Blue

Red

Pulsing

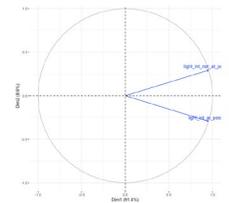

Statistical Analysis: See Me After

1) Data processing and covariate selection

Check Correlations

PCA Light Intensity

2) General and Generalized linear mixed models

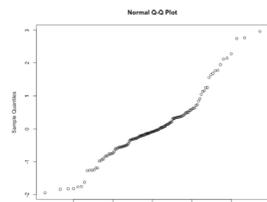

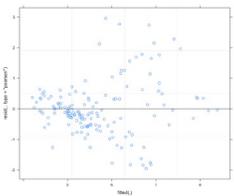

- **Fixed effect:** Color, Frequency, + Interactions
- **Random effects:** Bird ID
- **Covariates:** Light Intensity, Trial Order, Light Position

3) Model Selection

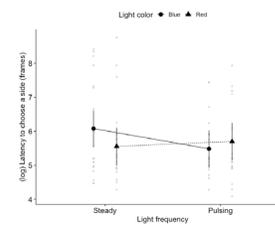

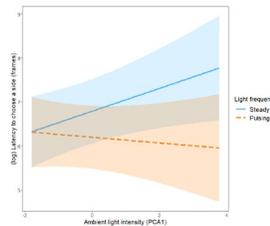

Simple → Complex

AIC to select model of best fit

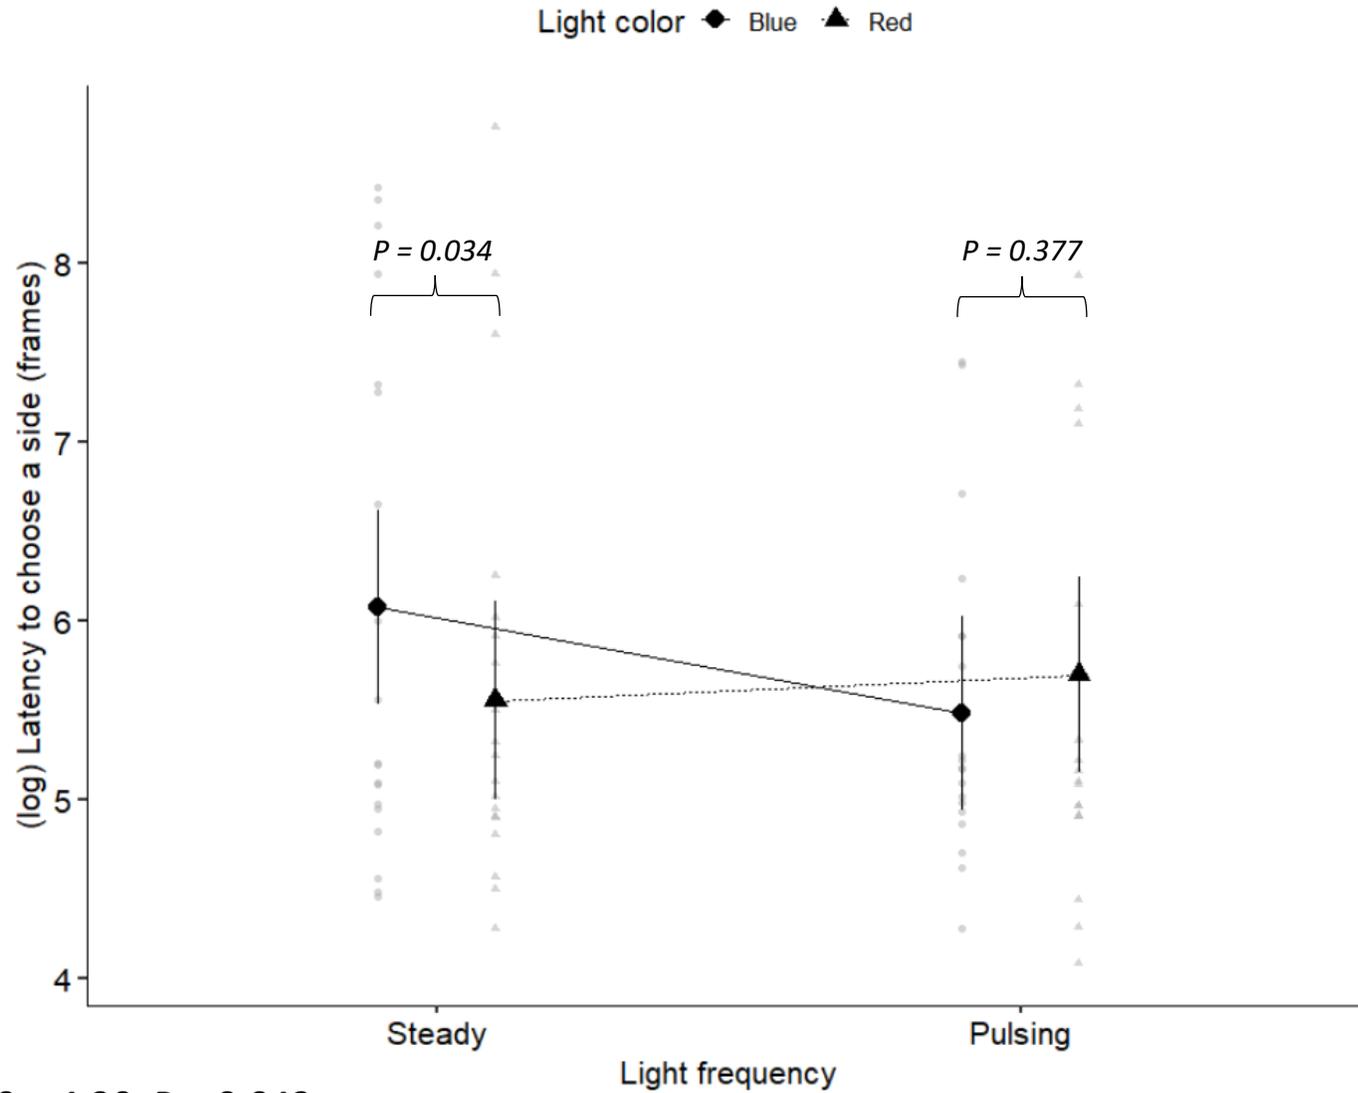

4) Check model assumptions transform if needed

5) Interpreting Fixed and Random effects

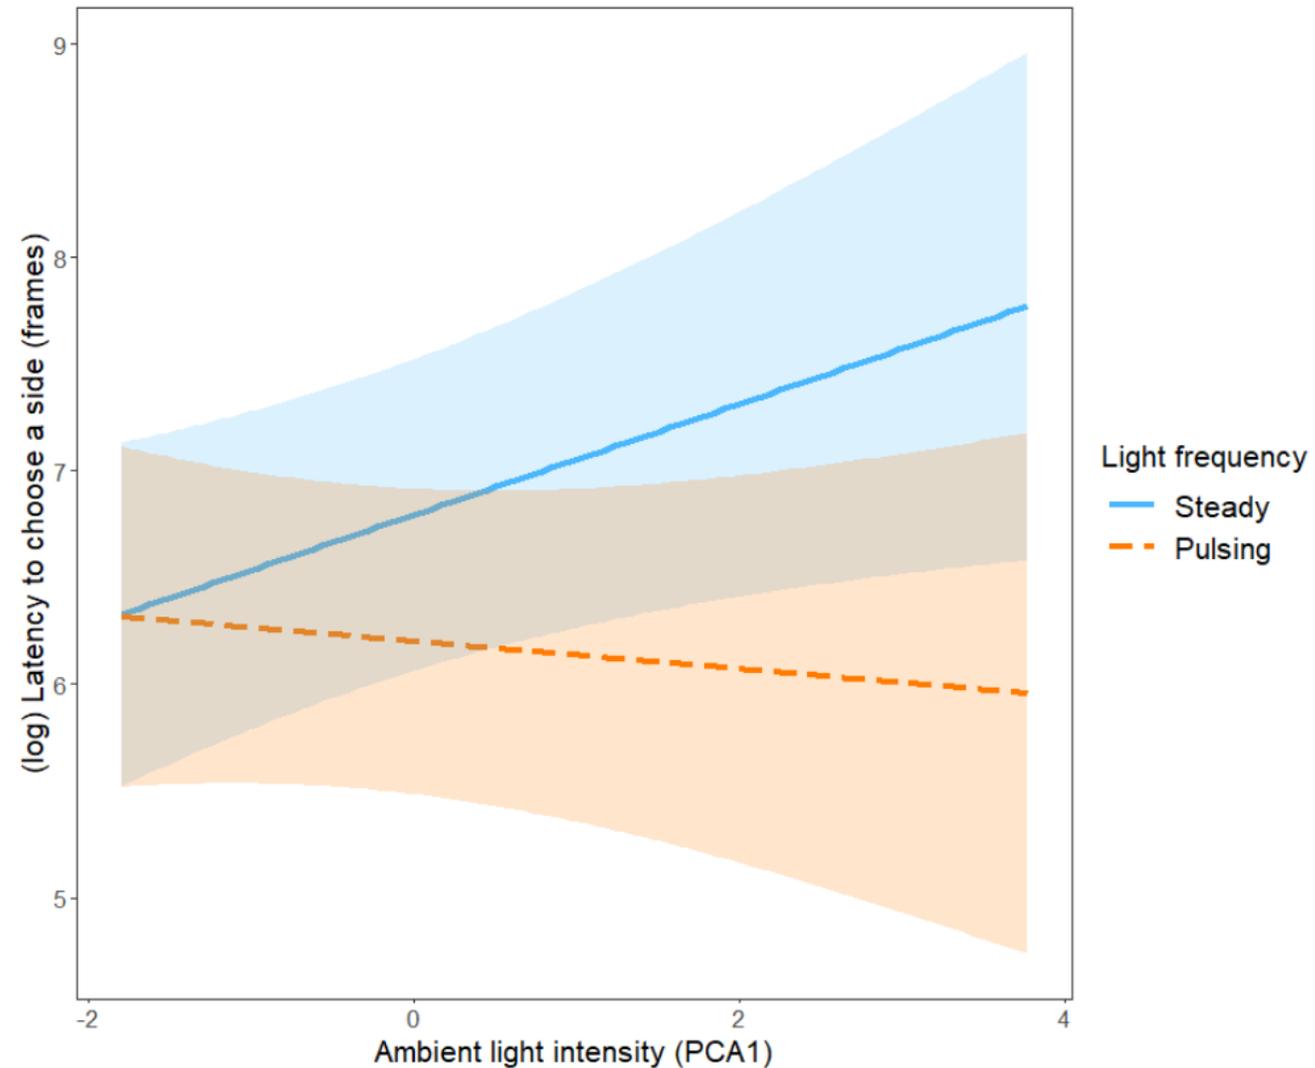

Latency: geese responded sooner to red steady than blue steady lights

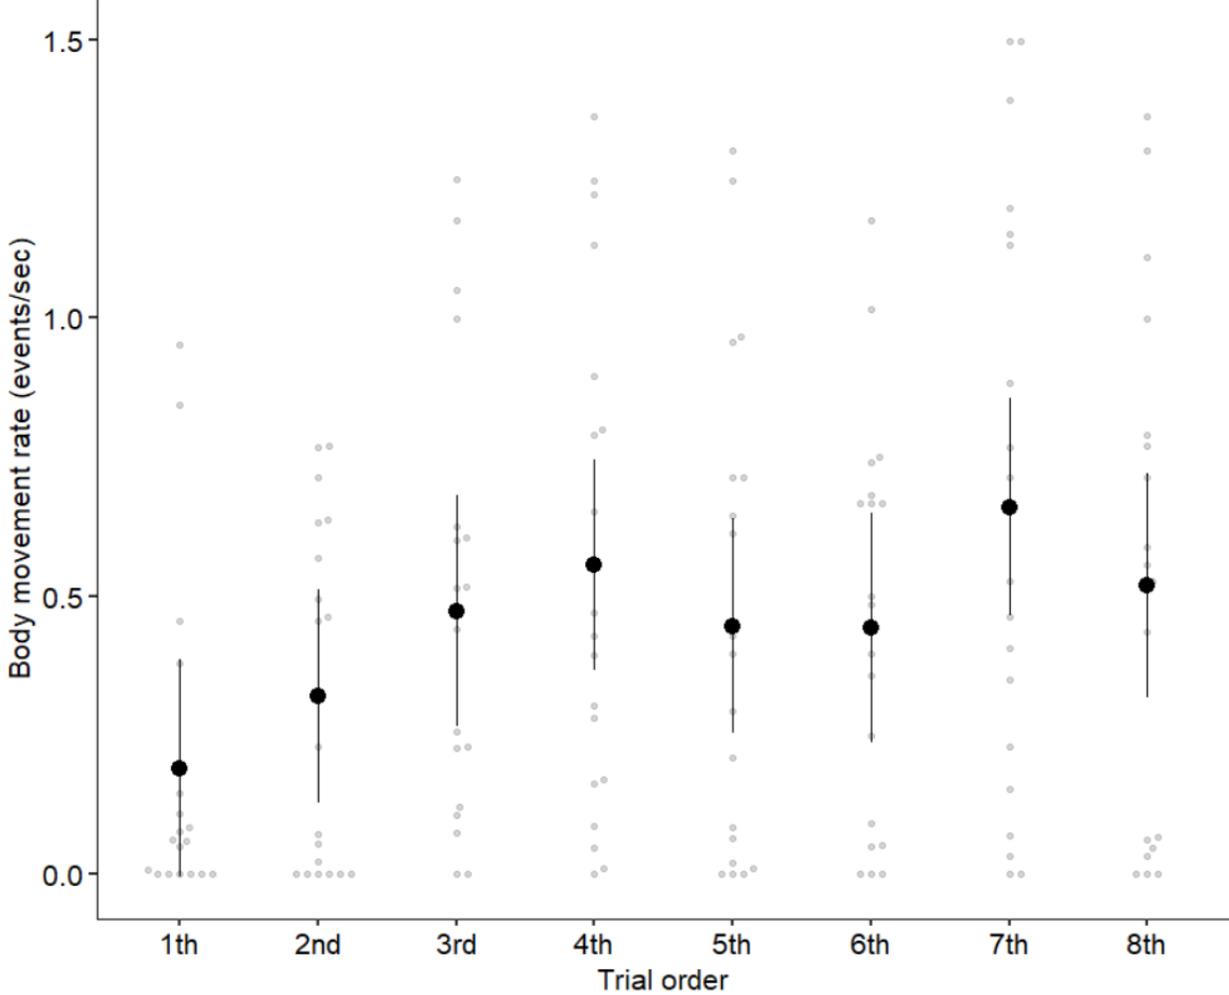

Color X Frequency: $F_{1, 119} = 4.20$, $P = 0.043$

Latency: geese delayed their responses when the steady light was under higher light intensity

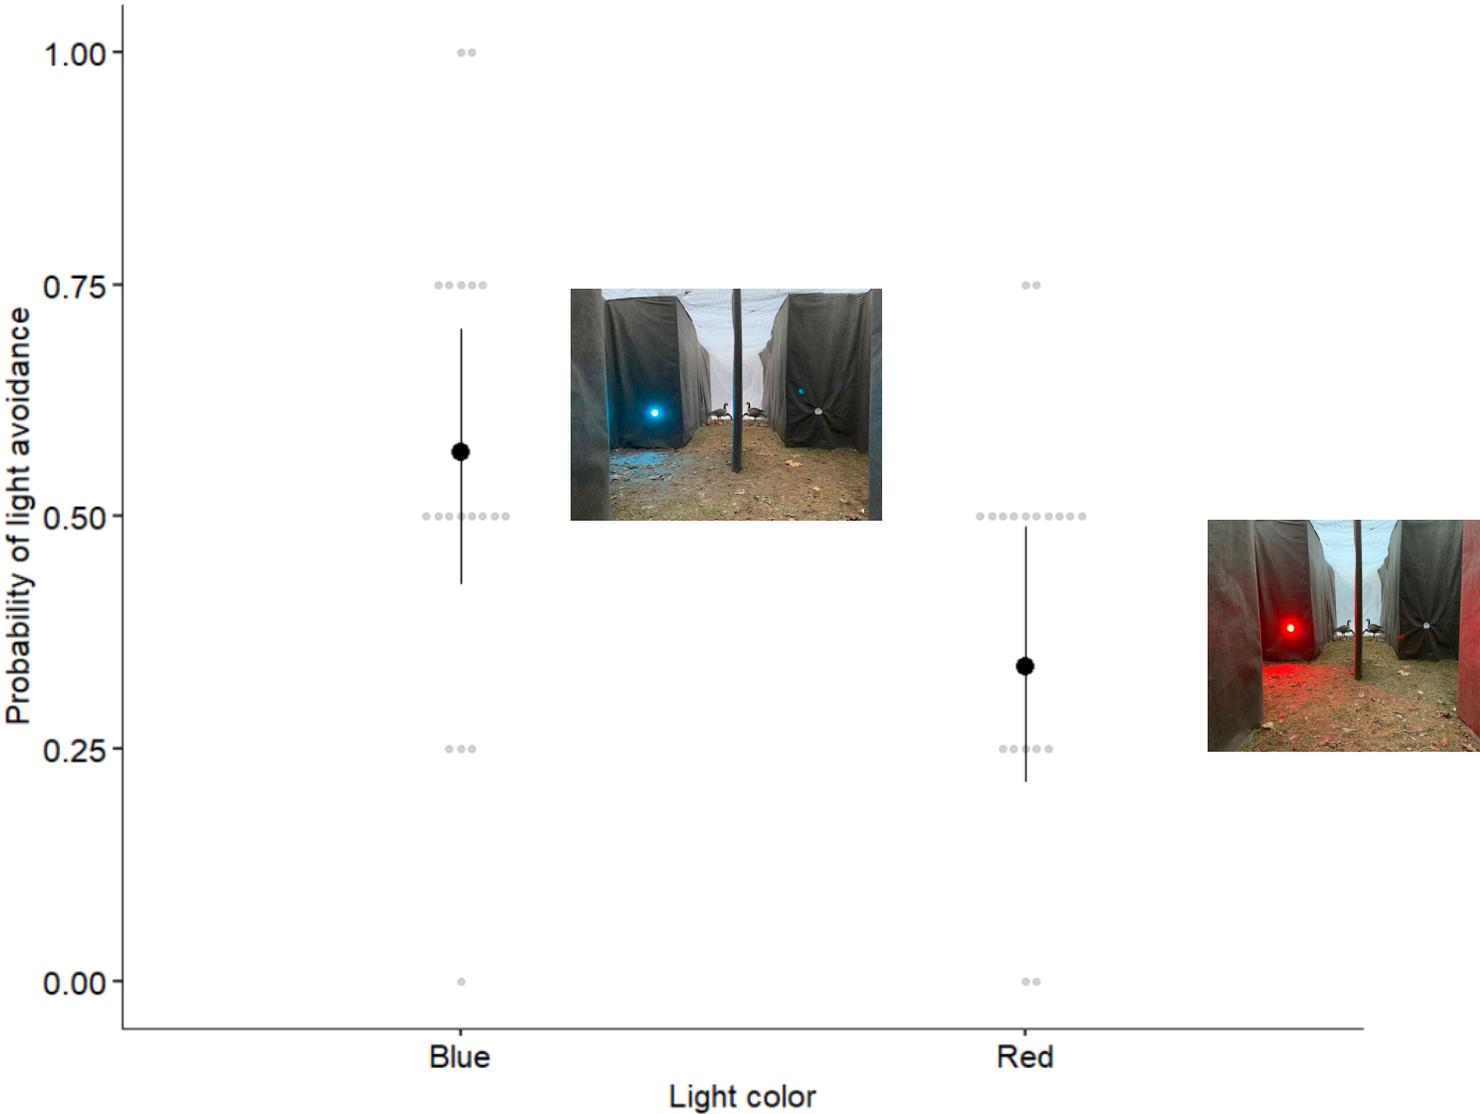

Frequency X PCA1: F 1, 128 = 5.40, P = 0.021

Body movement rate: before making a choice, geese varied the pace of their body movements with the number of exposures to the lights

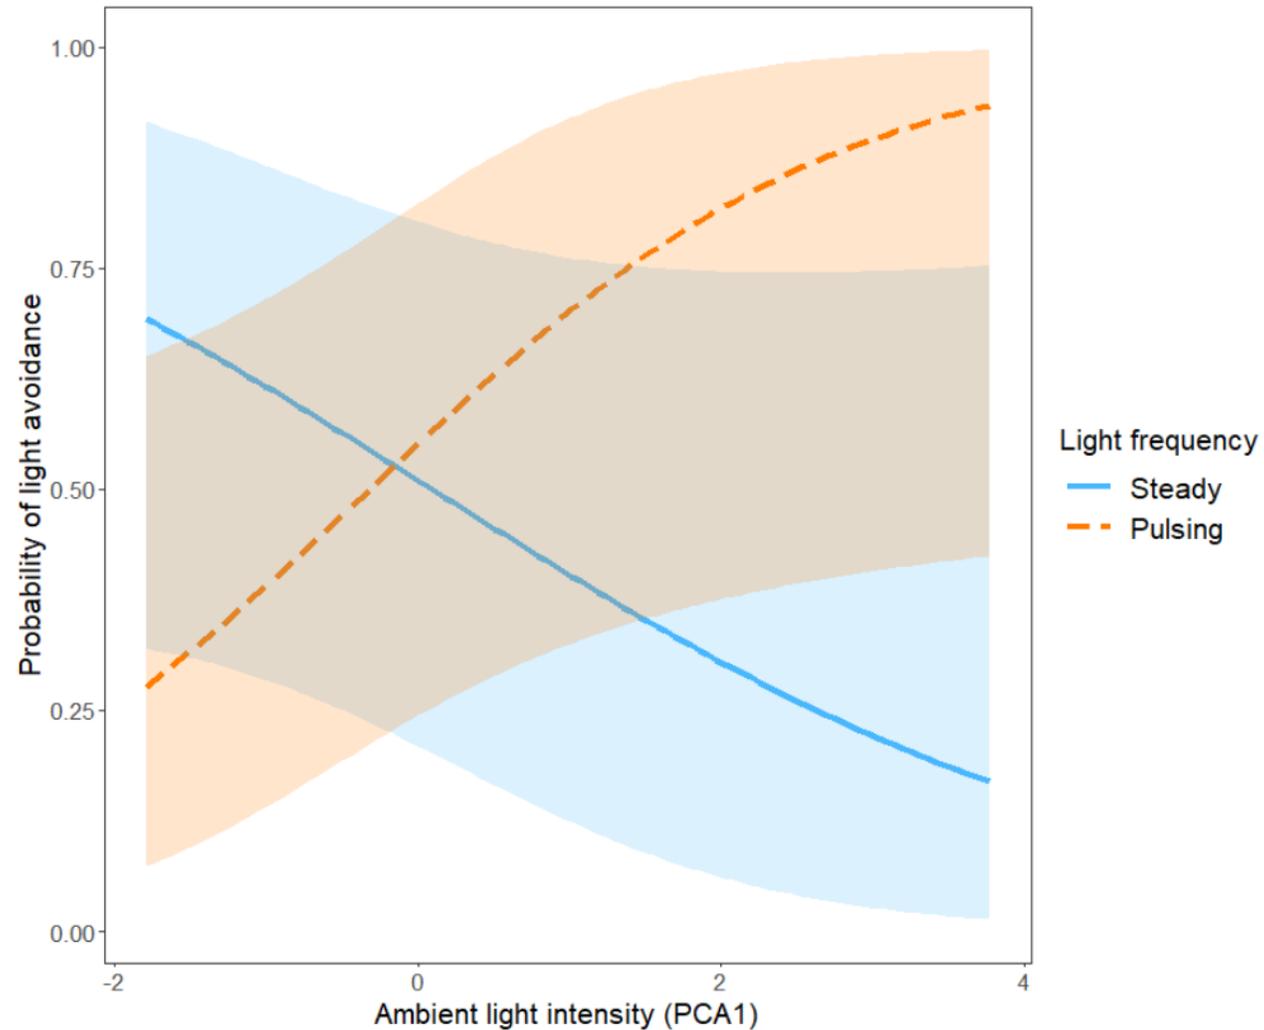

Trial order: $F(7, 107) = 2.27, P = 0.034$

Avoidance: geese avoided blue lights (471 nm) more than red lights (627 nm)

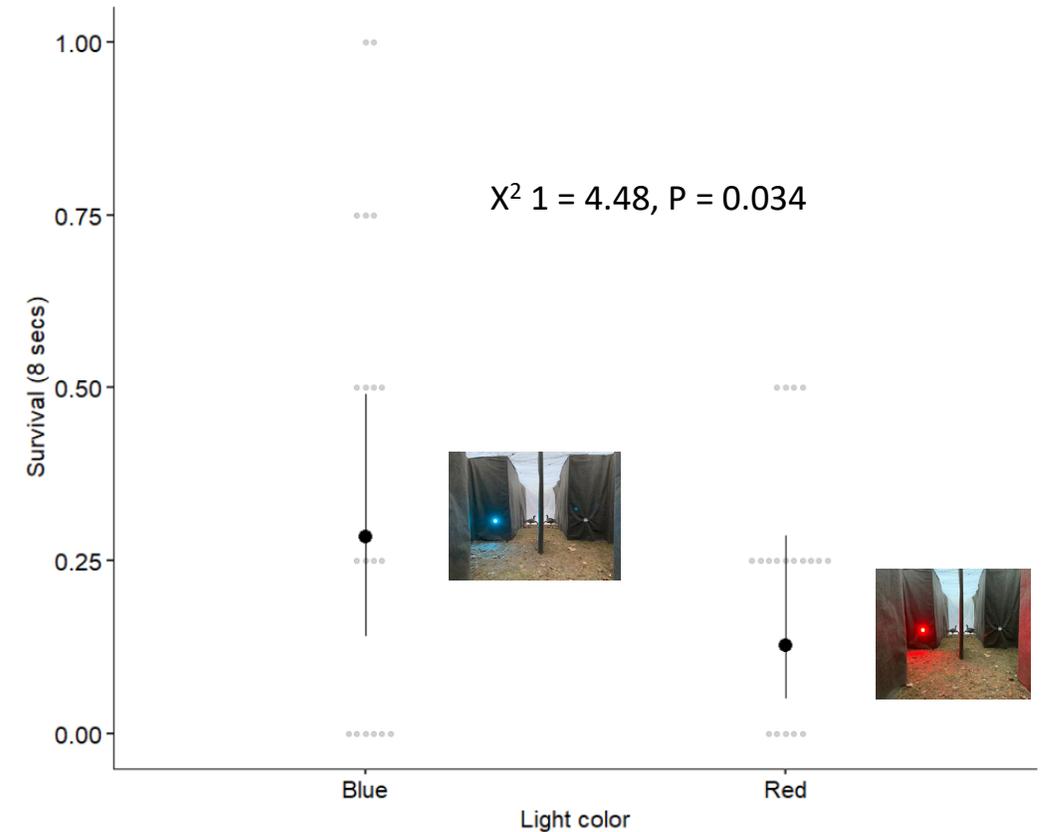

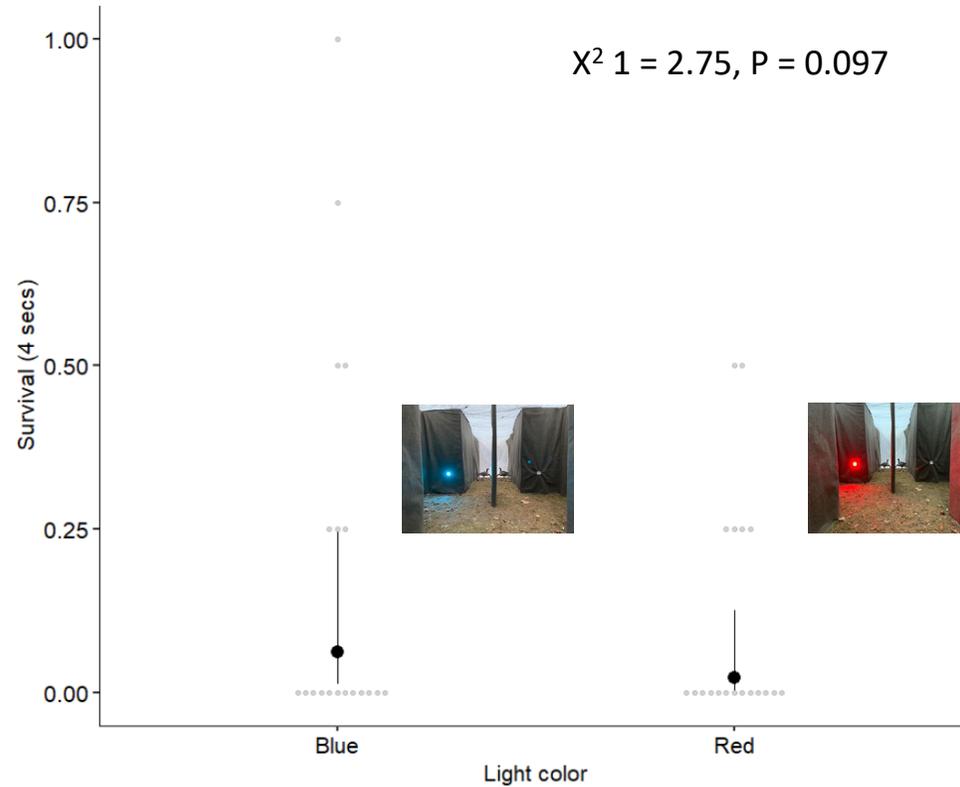

Color: $X^2_1 = 2.27$, $P = 0.034$

Avoidance: geese had higher chance of avoiding steady lights with low and pulsing lights with high ambient light intensity

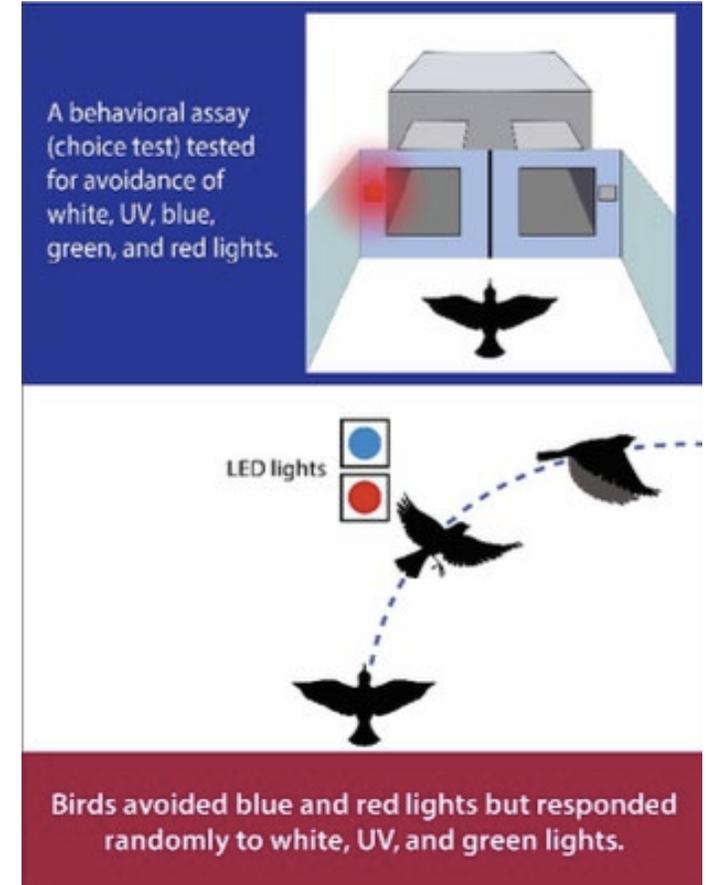

Frequency X PCA1: $X^2_1 = 11.59$, $P < 0.001$

The effects of light color on goose “survival” increased with the amount of time the animal had to decide a response to the lights

Conclusions

- Behavioral experiments under controlled conditions are essential to the evaluation the performance of lights.
- Lights tuned to the Canada goose eye with high retinal stimulation do not perform equally.
- Blue lights (471 nm) performed significantly better at generating avoidance behavior than red lights (627 nm)
- Blue lights of (470 nm) generate avoidance response in Brown-headed Cowbirds (Goller et al. 2018)
- Ambient light intensity can have a substantial effect on the performance of lights – this suggests the need for flexibility (steady vs. pulsing lights) depending on environmental conditions (sunny, cloudy).

Next Step

- 1. Repeated exposures to light can individual birds behaving differently to lights– need to study effects to light sensitization?**
- 2. Light intensity could also affect behavior – we chose light intensities not high enough to avoid sensory overwhelming effects (leading to freezing) - need to study LED light thresholds**
- 3. Estimate the intensity needed for a goose to resolve a light source given a certain ambient intensity**

Future Direction

Increasing the distance at which an animal detects the approaching aircraft provides more time for the animal to enact an escape response and avoid the collision.

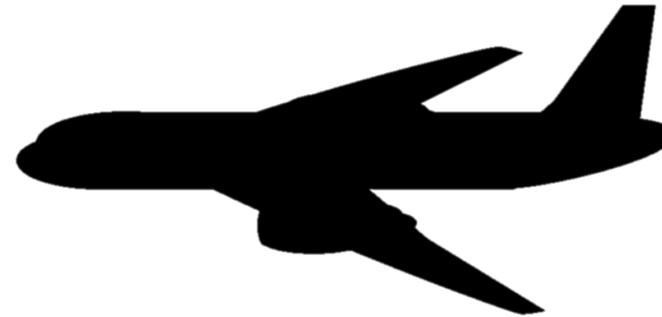

Lower probability of survival

Animal

Detection Distance

Aircraft

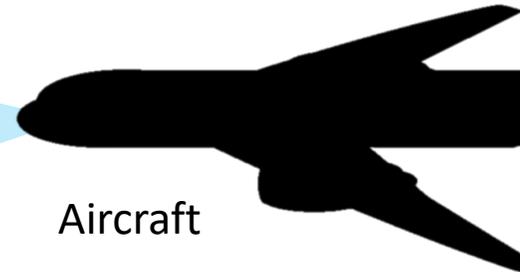

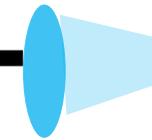

Higher probability of survival

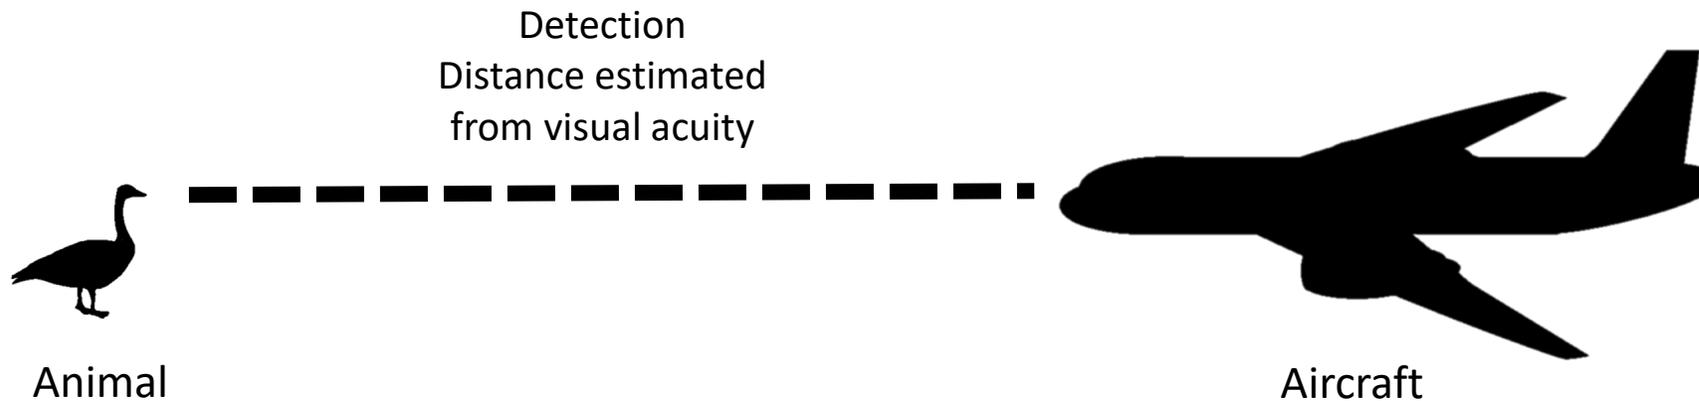

Animal

Detection Distance

Aircraft

We have equations to estimate **avian** detection distance of opaque objects

Visual Acuity Formula:

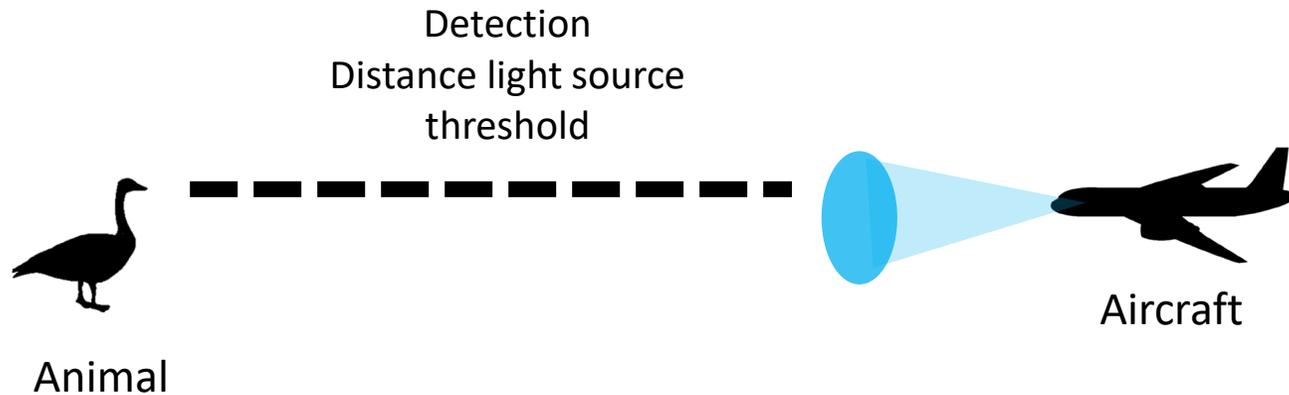

$$RMF = \frac{2\pi PND}{360}$$

$$F_n = \frac{RMF}{2} \sqrt{\frac{2D}{\sqrt{3}}}$$

$$Detection\ Distance = \frac{r}{\tan\left(\frac{F_n}{2}\right)}$$

GAP: we do not have a framework to estimate avian detection distance of light sources

Estimating the detection distance of a light source for the Canada goose

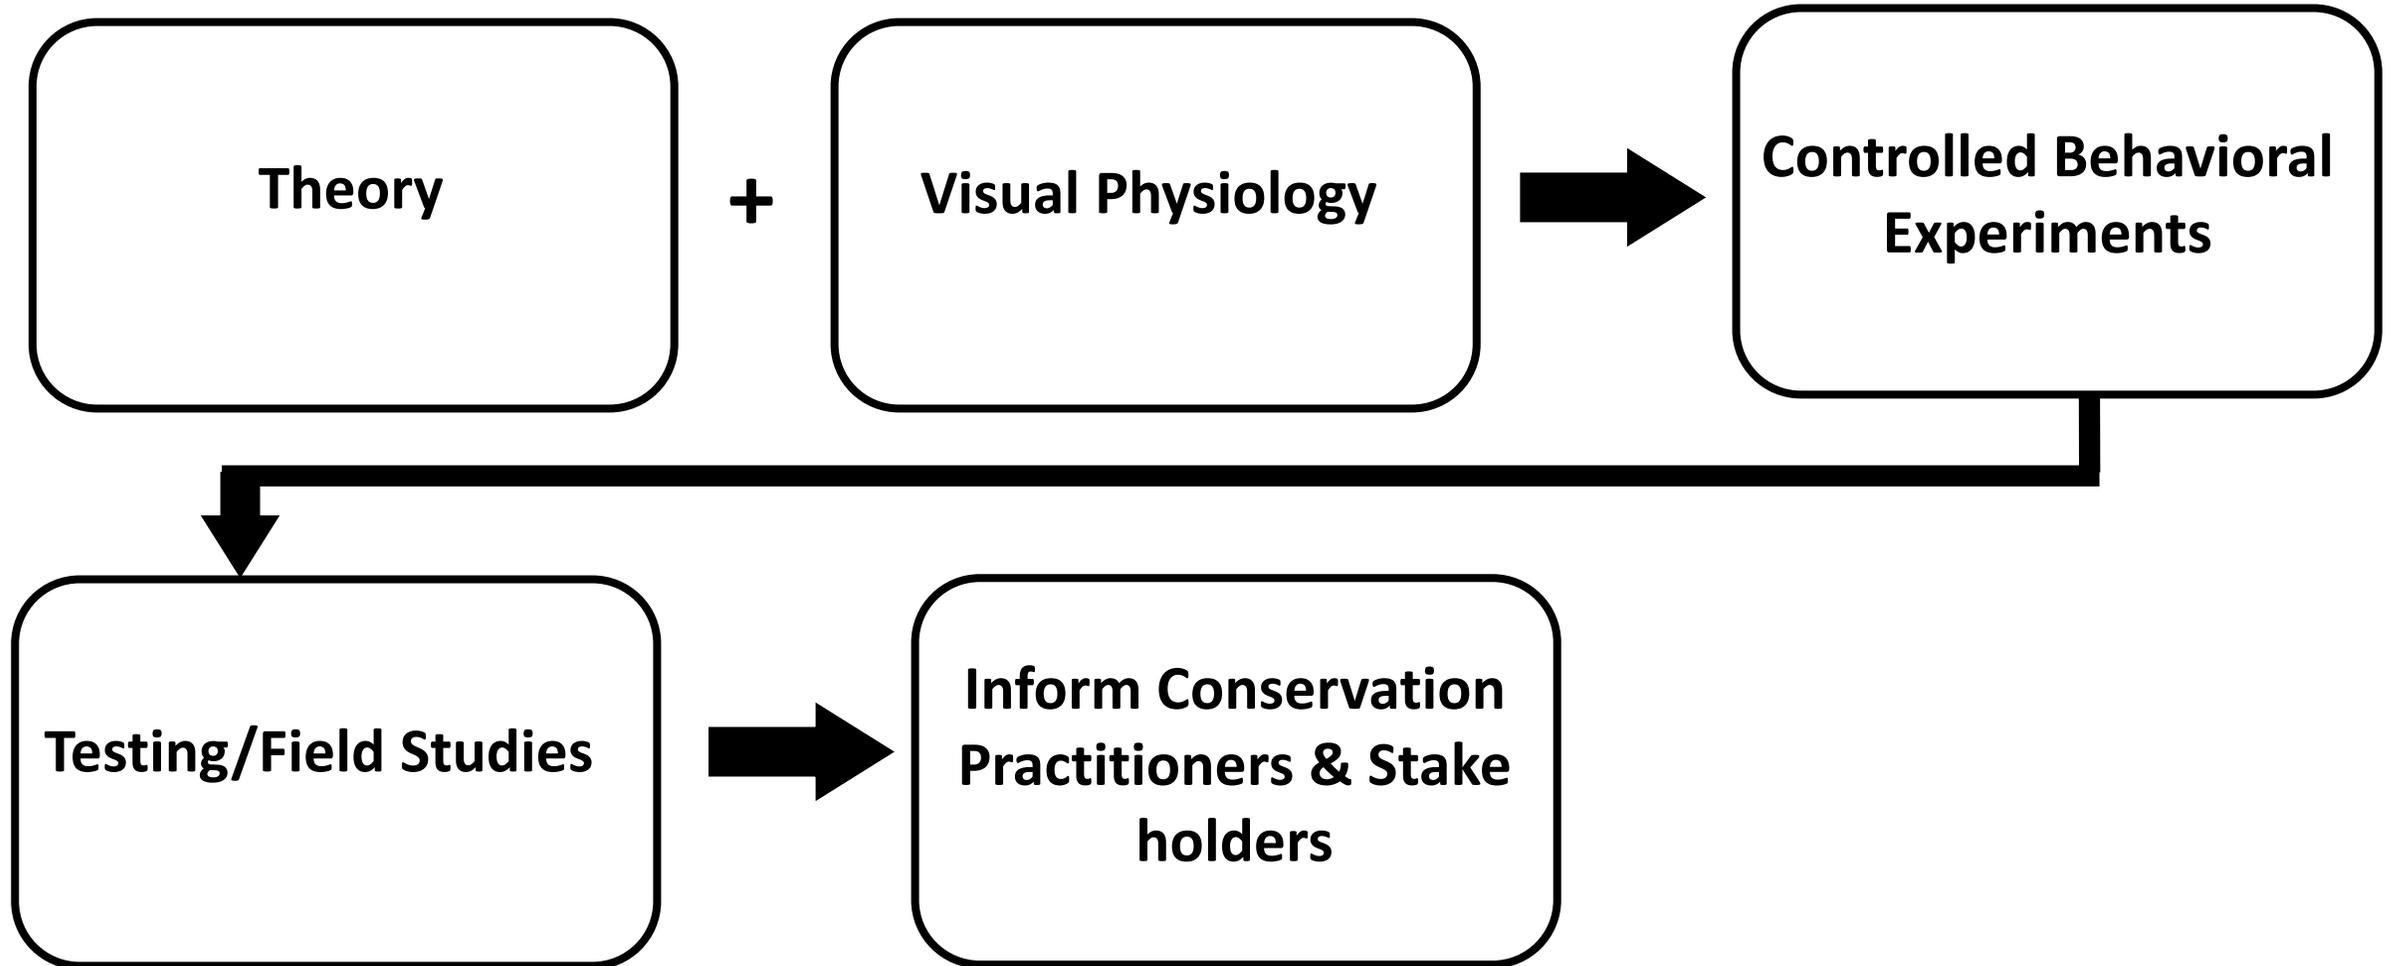

Light Source Detection Formula:

$$r \cong \frac{2}{c} W \left[\frac{cA}{8\sqrt{3}} \sqrt{\frac{E\Delta t}{1 + \sqrt{1 + (2.8d^2 N_0 + 4X)\Delta t}}} \right]$$

$$N_0 = \left(\frac{\pi}{4} \right) q\tau \int_{\lambda_1}^{\lambda_2} \left(1 - e^{-kR(\lambda)l} \right) L_b(\lambda) d\lambda$$

This is a KEY step towards developing new technology

Our general approach: build lights around the avian eye that birds avoid
