Scale-dependent Decisions of a Red-tailed Hawk and a Carolina Wren

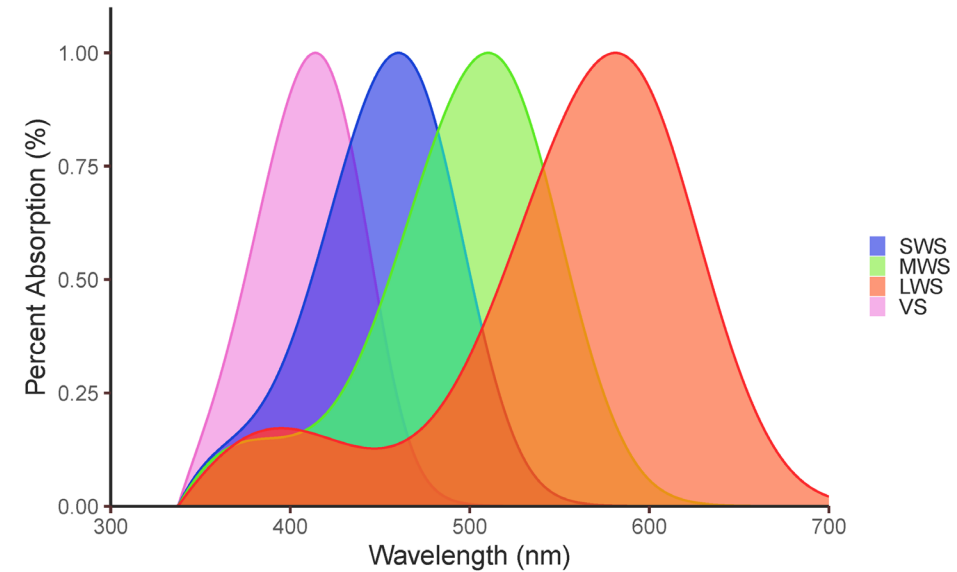

Avian vision is different from human vision

Human Vision

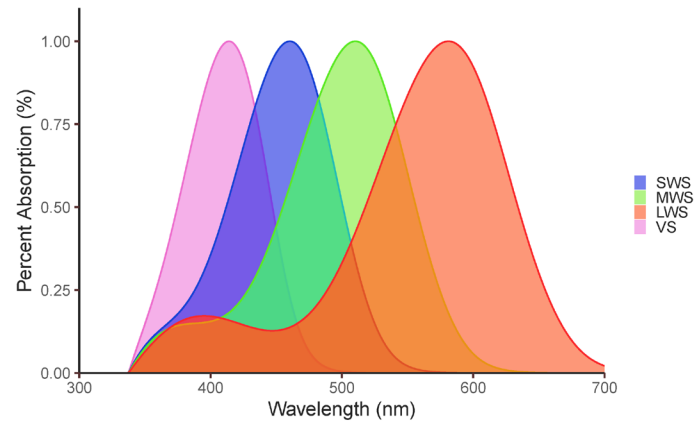

Bird Vision

More cone types

More colors
perceived

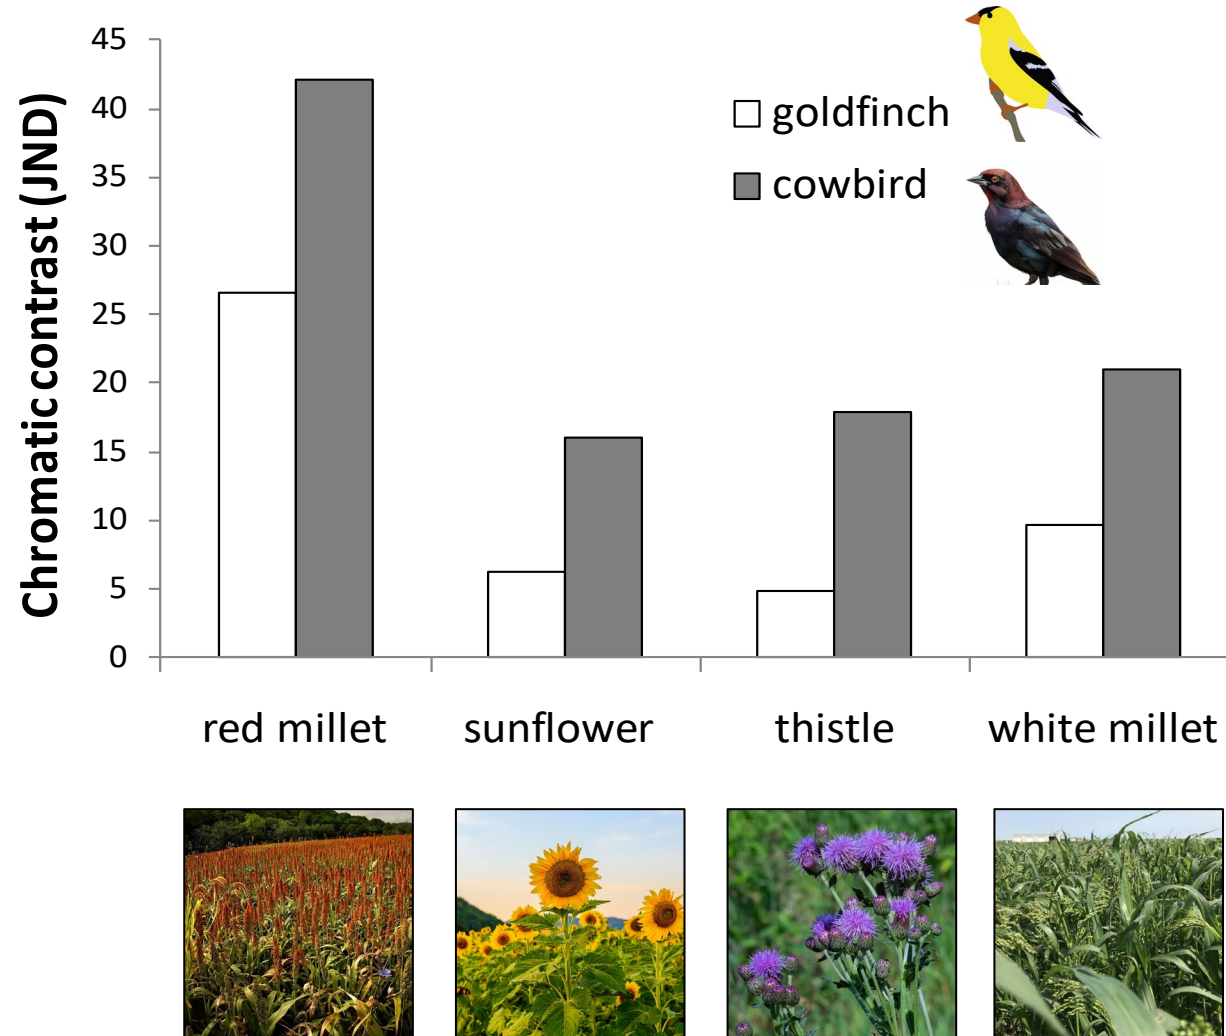

Having four types of cones increases the visual contrast of the vegetation

Generating a unique visual signature

There is considerable between-species variation in visual physiology and visual perception

Different bird species perceive slightly different visual signatures on landscape elements

Can we shift the visual signature of a landscape element from the visual perspective of a bird species?

To what extent can this shift influence the species' behavior?

Testing the terrain hypothesis: Canada geese see their world laterally and obliquely

LED lights illuminating an area could alter the visual signature of a landscape element to either increase or decrease its visual conspicuousness to the avian eye, prompting a change in behavior

Proof-of-concept study: bird-solar interactions

Funded by the US Air Force

Lake effect hypothesis

Solar facilities and bodies of water have similar visual signatures from the perspective of birds

Birds may be “attracted” to solar facilities, which may act as sensory “traps”

Can we shift the visual signature of solar panels so birds avoid them?

© Christopher Nicolai

- Model species: mallard (*Anas platyrhynchos*)

- Mallard visual system components
- Visual models to quantitatively assess mallard visual perception
- Behavioral experiment 1:

- Visual signature of solar panel vs. water source
- Attraction/avoidance responses to solar panels vs water source

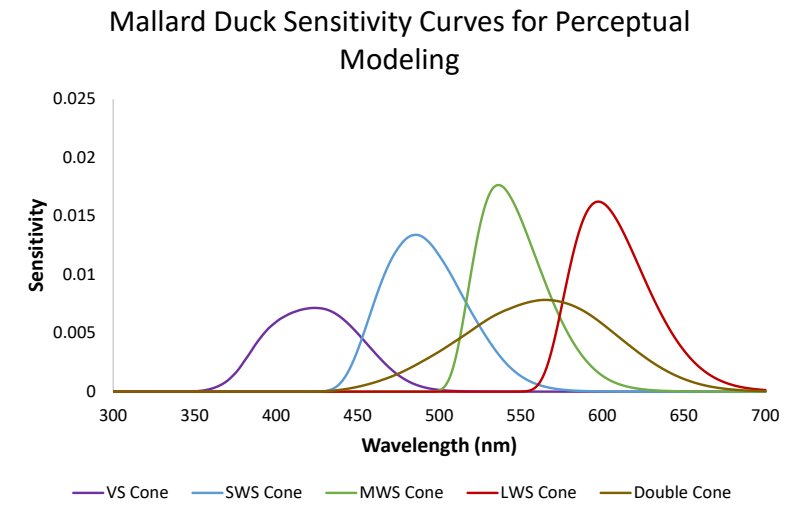

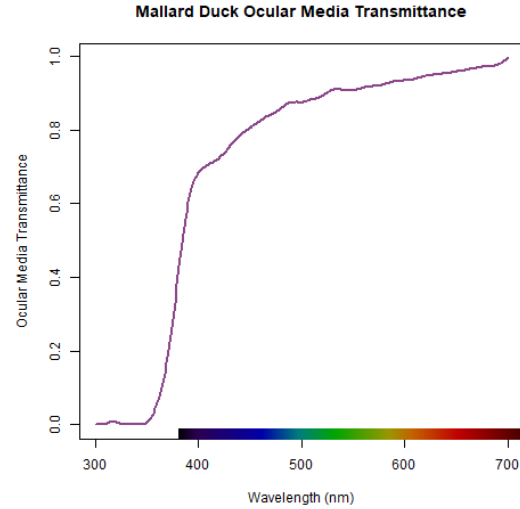

- Behavioral experiment 2:

- Visual signature of the solar panel shifted with an LED light veil
- Attraction/avoidance responses to solar panels with light veil vs solar panels without light veil

Mallard visual system

Violet sensitive visual system

Visual models estimate quantitatively how much an object stands out from the background

Chromatic contrast

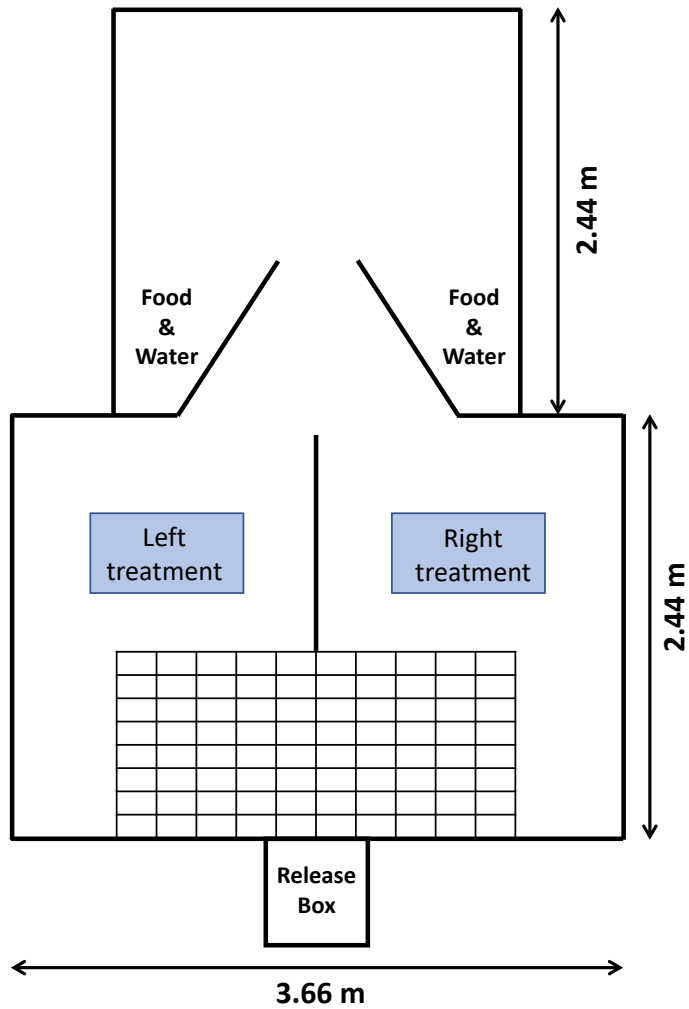

Achromatic contrast

High \longrightarrow Low

Photon catch and receptor noise model
(Osorio & Vorobyev 1998)

Behavioral experiment 1

20 adult wild-type mallards

solar vs. water

Proportion of individuals that chose a treatment

No significant difference choosing water vs. solar panel

Generalized Linear Mixed Model with intercept only and individual ID as random factor ($z = 0.95$, $P = 0.345$)

Mallards did not discriminate behaviorally between water and solar panels

Sensory mechanism?

Chromatic contrast solar panel vs. water

($F_{1,78} = 95,913$, $P < 0.05$)

Achromatic contrast solar panel vs. water

($F_{1,78} = 21,295$, $P < 0.05$)

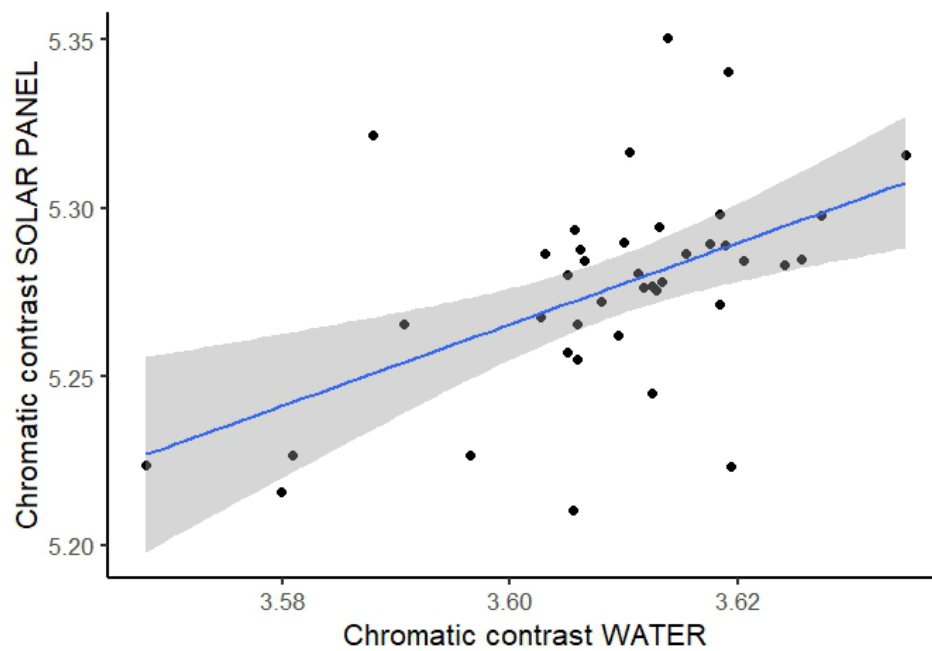

★ small differences

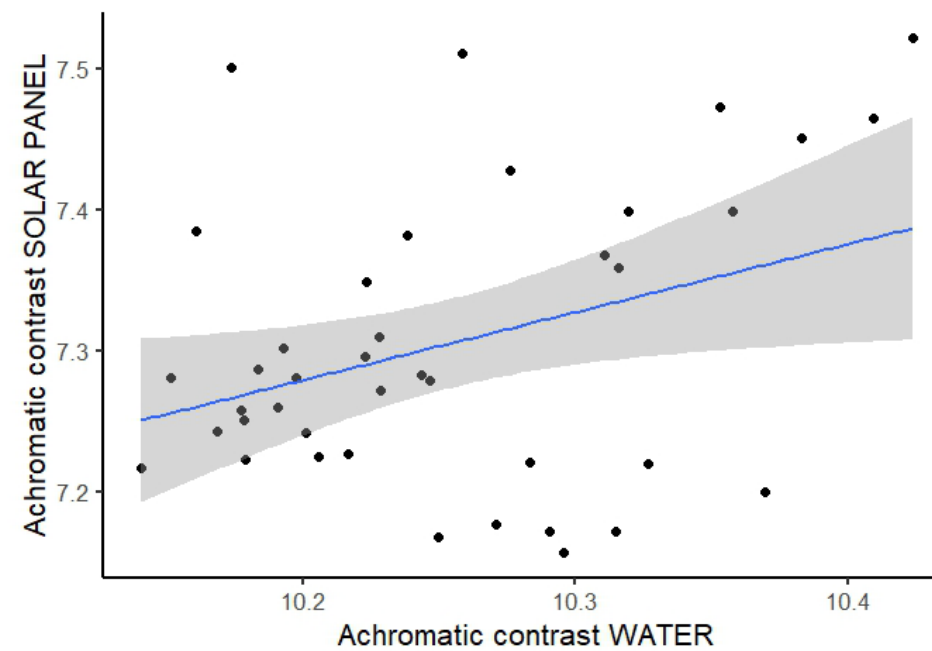

Chromatic contrast

Achromatic contrast

Person's correlation $r=0.51$, $P < 0.001$

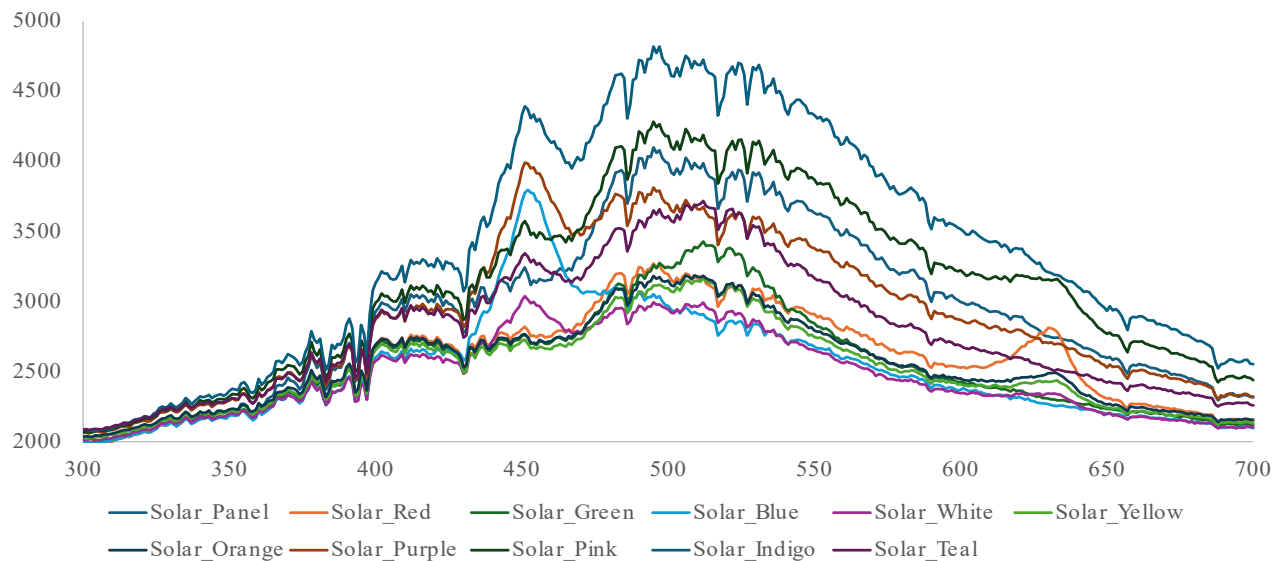

Person's correlation $r=0.35$, $P = 0.028$

Take-homes (I)

- The visual differences between the water and the solar panel may not have been enough (from the mallard viewpoint) to affect choice behavior.
- We found a potential sensory mechanism (chromatic contrast) to explain the visual similarity between water and solar panels.

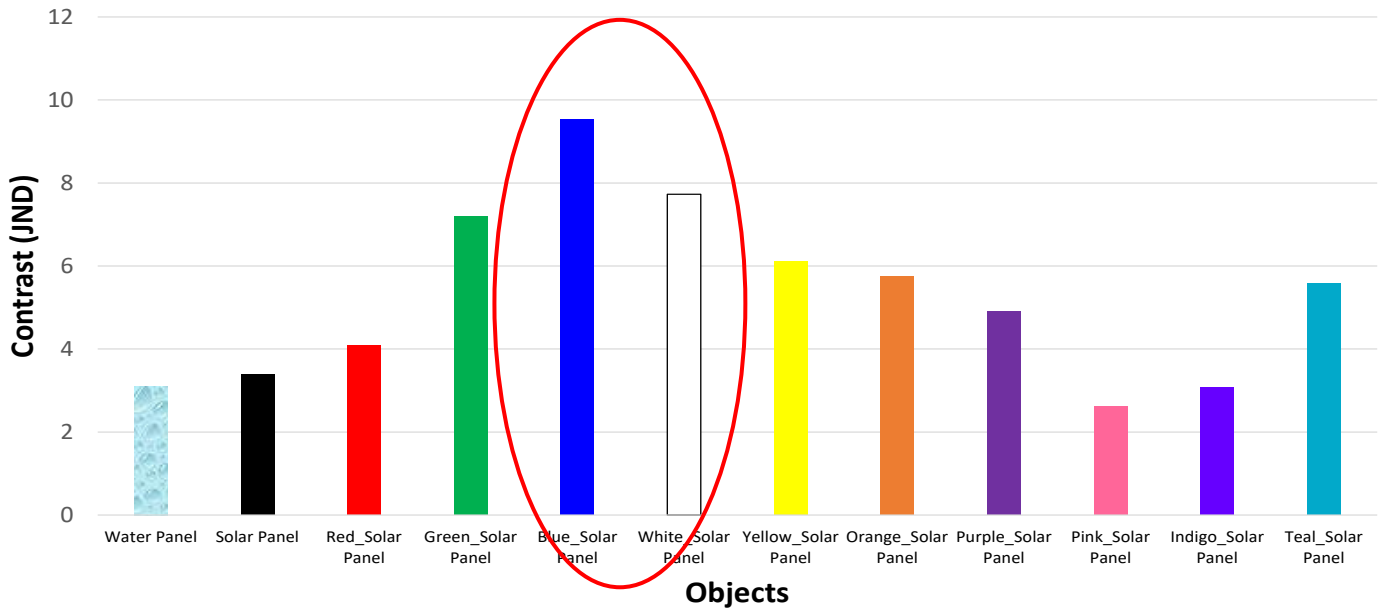

Shifting the solar panel visual signature with LED illumination

Chromatic contrast

Chromatic Contrast of the Solar Panels with Light Veils

Behavioral experiment 2

30 adult wild-type Mallards

Blue LED light veil vs. bare solar panel

Bare solar panel vs. blue LED light veil

White LED light veil vs. bare solar panel

Bare solar panel vs. white LED light veil

LED light veils changed the visual signature of the solar panels

($F_{1,118} = 13,098$, $P < 0.001$)

($F_{1,118} = 5,204$, $P < 0.001$)

Chromatic contrast

~40Klux

Behavioral responses to white LED light veil

Mallard ducks did not prefer or avoid the white lights significantly ($z = -0.52$, $P = 0.606$)

~40Klux

Peak wavelength: 462 nm

Behavioral responses to blue LED light veil

Mallard ducks avoided the side of the arena with the blue light veil ($z = 2.04$, $P = 0.041$)

The blue light performed significantly better than the white light in generating duck avoidance responses

Generalized Linear Mixed Model with individual ID as random factor ($X^2 = 6.78$, $P = 0.009$)

Take-homes (2)

- High intensity (~40Klux) blue (462 nm) LED lights appear to not only shift the visual signature of the solar panels but also generate avoidance behavior.
- Ducks do not respond to all lights equally, as white LED lights led to a random behavioral response.

Applications to airports

- Based on FAA data (1990- 8/20/2025)
 - Number of reports where strikes occurred near ground level (0-50 ft AGL): 87,681 out of 326,195 strikes (26.9%)
- Example species:

Species	Strikes 0-50 ft AGL	Percentage of strikes that occurred 0-50 ft AGL
Mourning dove	4,221	25.2
American kestrel	2,388	24.0
European starling	2,057	30.5
Rock pigeon	1,629	35.4
Red-tailed hawk	1,589	36.2
Bald eagle	268	46.7

Birds are using different landscape elements (perching, nesting, or foraging) in the airport

LED illumination tuned to the visual system of target species might be used to shift the visual signature of key elements in the airport environment and potentially generate avoidance behavior

ANY QUESTIONS?
